

VS.

Are life and health insurance aligned?

Who sets standards of health for life insurance companies?

Are they based on health or insurance goals?

80/20 Rule

The 80/20 Rule generally requires insurance companies to spend at least 80% of the money they take in from premiums on health care costs and quality improvement activities. The other 20% can go to administrative, overhead, and marketing costs.

The 80/20 rule is sometimes known as Medical Loss Ratio, or MLR. If an insurance company uses 80 cents out of every premium dollar to pay for your medical claims and activities that improve the quality of care, the company has a Medical Loss Ratio of 80%.

- As costs go up – profits go up
- An incentive for promoting poor health
- At odds with the life insurance goals

CHRONIC DISEASES IN AMERICA

6 IN 10

Adults in the US
have a **chronic disease**

4 IN 10

Adults in the US
have **two or more**

THE LEADING CAUSES OF DEATH AND DISABILITY
and Leading Drivers of the Nation's **\$4.1 Trillion** in Annual Health Care Costs

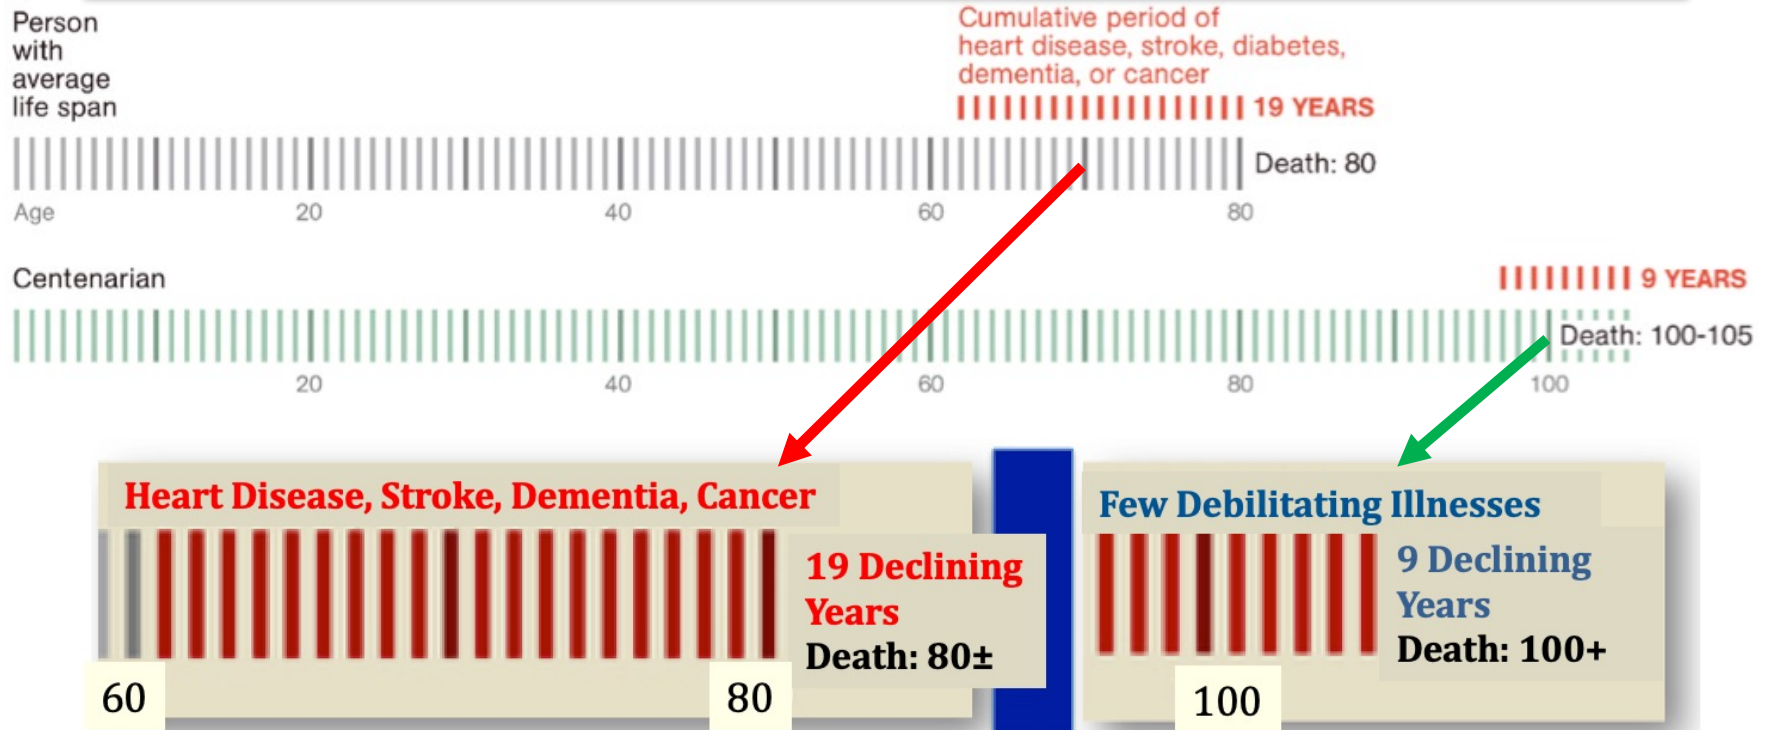

In 1900, almost one-half of all deaths were due to acute conditions, yet as we close the twentieth century, only about one-in-ten deaths is due to an acute condition (CDC, 1997).

One hundred years ago only one-in-six people died of a chronic condition.

16% to 60%

Getting to 100 candles

Living to 100 grants a person 20 extra years of longevity.
Significantly – they experience 30 years of extra “healthspan.”
when compared to those who die at 80 (or younger).

Life Insurance Goal: Clients live to 100

Health Insurance Goal: Patients live to 80

Reference Ranges and What They Mean

Fundamental OBJECTIVE measurements are flawed

Board Approved

- **A normal result in one lab may be abnormal in another:** *You must use the range supplied by the laboratory that performed your test to evaluate whether your results are “within normal limits.”* While accuracy of laboratory
- **A normal result does not promise health:** While having all test results within normal limits is certainly a good sign, it's not a guarantee. For many tests, there is a lot of overlap among results from healthy people and those with diseases, so there is still a chance that there could be an undetected
- **An abnormal result does not mean you are sick:** A test result outside the reference range may or may not indicate a problem. Since many reference values are based on statistical ranges in healthy people, you may be one of the healthy people outside the statistical range, especially if your value is

When biomarker ranges of normal are incorrect, populations become less healthy

Figure 2. Broadening of reference range as the population becomes less healthy (blue to red curves) and narrowing of the reference range as the population becomes healthier (blue to green curves). The transition from the starting population to the less healthy population is reflected in the changes to laboratory reference ranges for WBC counts.

Health

Chronic inflammation is long lasting, insidious, dangerous. And you may not even know you have it.

“Unlike acute inflammation, which benefits health by [promoting healing and recovery](#), chronic inflammation is characterized by **persistent increases in inflammatory proteins** all throughout the body and can damage health and promote **several major diseases**,” says George Slavic, associate professor of psychiatry and biobehavioral sciences at UCLA.

Health and Disease is a Continuum

ICD-10: 70,000 Codes

Real World: 5 Mechanisms

Increasing Time Require
To Reverse Condition(s)

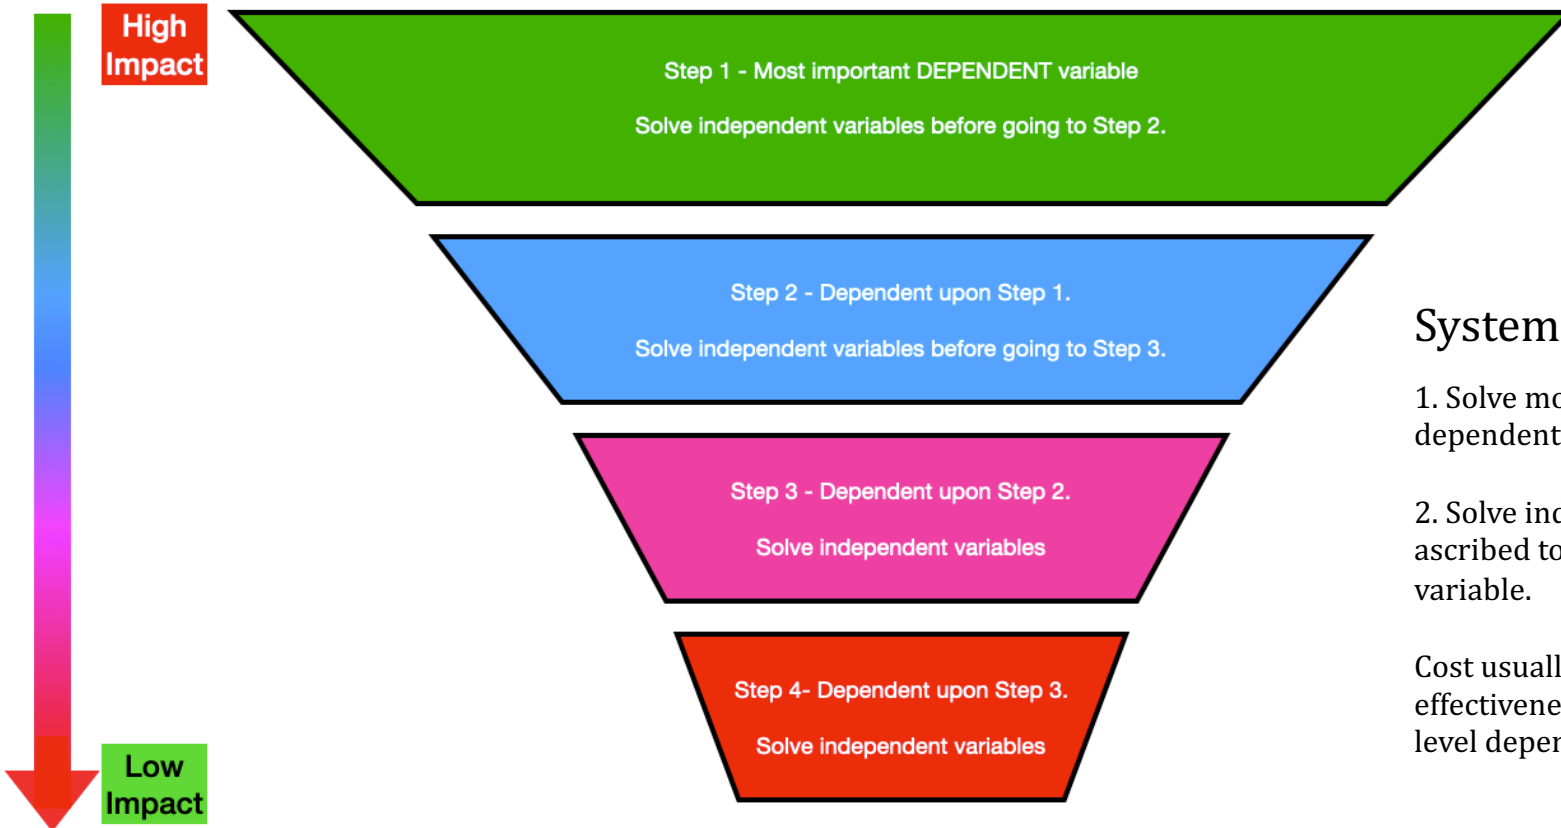

5 mechanisms of Disease

There are ~70,000 or medical diagnoses. However, my team operates based on 5 disease mechanisms that contribute to most morbidity & mortality. These mechanisms are:

1. Poor micronutrient status from poor diets, behaviors, or poor absorption.
2. Thrive vs survive. Stressors that create vulnerability.
3. Stealth and chronic infections and toxins with infections being the greatest offender. (When we die, we are “pickled.” They are already there!
4. Perpetual low-grade inflammation caused by infections, specific sensitivities, and processed foods.
5. Lack of autophagy due to sedentary lifestyle and constant eating.

This established a roadmap to prioritization.

Hierarchy of Health

Systems Approach:

1. Solve most impactful dependent variable first.
2. Solve independent variables ascribed to each dependent variable.

Cost usually **increases** and effectiveness **decreases** at lower-level dependent variables.

Health – Disease Barometer – Easily Understood Representation

Breakdown into categories of risk

Mechanisms and categories of risk are not the same.

A mechanism may increase risks in several categories.

However, these categories are based on objective biomarker measurement and provide a foundation for understanding the cause/effect relationship between mechanisms and outcomes.

The breakdown into biomarker specificity for diseases

CDT Report	Medium Risk	DATE	2019-01-18	CDT	6.5	Score
Diabetes	Glucose	A1C	Insulin	Triglycerides	Uric Acid	Diabetes
Optimal	65 - 80	4 - 5	2 - 6	<100	4 - 6	0 to 10 Scale

What is Your Risk of Sudden or Premature Death?

Understanding Your Labs: Individual lab values are important. MORE important is the story your labs tell about your future health, when taken together.

Optimal Values: We have established science-based optimal biomarker ranges through an exhaustive search of the worldwide medical literature. Our *normal (optimal)* values are those that show **no increase in excess early mortality risk** – based on sound statistical analysis

Your Chronic Disease Temperature (CDT): This single value, displayed at the top of your report, is the **combination of excess early mortality risk** from many important physiological biomarkers.

Your **CDT** value:

7.5

	Before	After	Change
CDT	7.5	3.5	4.0

Biomarkers – “Objective Data”

But reference ranges do.

Chronic Risk Markers: Ranking Specificity

1. Search “marker” & “diseases” – PubMed
2. Determine % association to specific diseases
3. Search “allintitle” marker & disease – determine the connection
4. Search for specific and all-cause mortality
5. Tertiles, quartiles, quintiles, deciles
6. Fit to “log-linear” relationship
7. Compare biomarker risks with hazard ratios for mortality
8. Evaluate cost-to-value relationship

CDT Markers: 6. WHITE BLOOD CELLS

Inflammatory biomarker score and cancer: A population-based prospective cohort study

Leavitt Morrison¹, Jari A. Laukkanen^{2,3}, Kimmo Ronkainen², Sudhir Kurl², Jussi Kauhanen² and Adetunji T. Toriola^{1*}

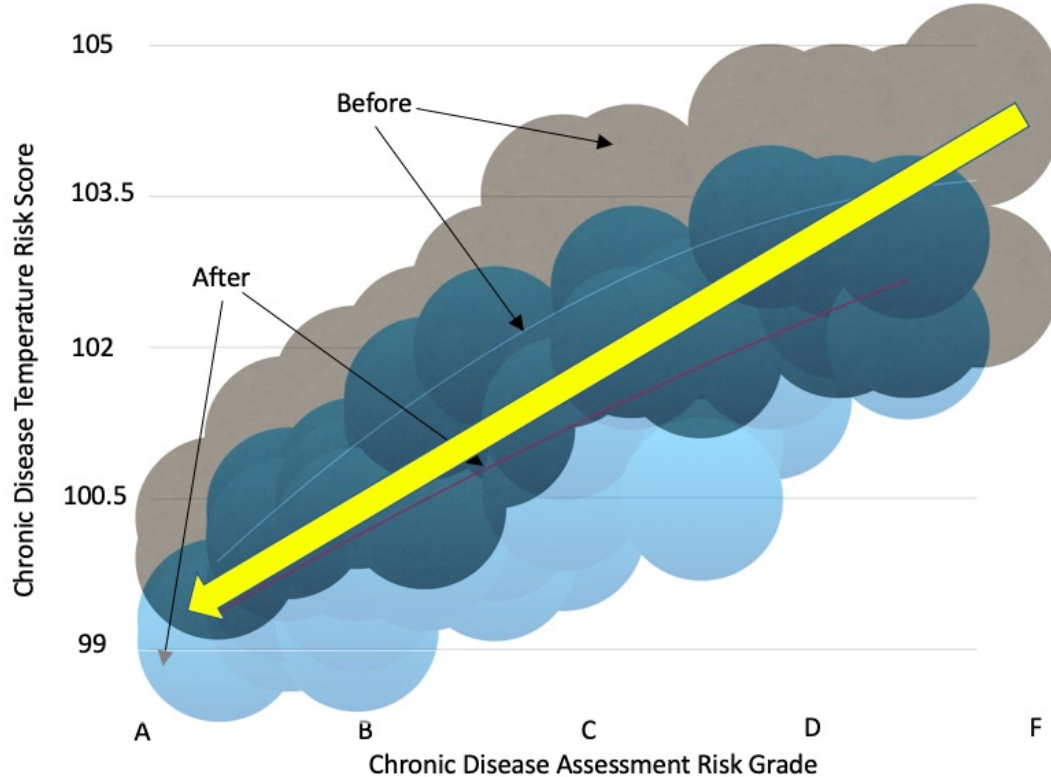

Abstract

Background: Inflammation is associated with cancer but there are conflicting reports on associations of biomarkers of inflammation with cancer risk and mortality. We investigated the associations of C-reactive protein (CRP) and leukocyte count with cancer risk and mortality using individual biomarkers, and an inflammatory score derived from both biomarkers.

Reduction in Chronic Disease Risk and Burden in a 70-Individual Cohort Through Modification of Health Behaviors
